#### Abstract

The size of a population $\widehat{N}$ in a dynamic setting can be estimated using closed population capture-recapture techniques. This entails drawing a sample from a sampling frame denoted by $n_{1}$, mark and return into the population. Thereafter, another sample is drawn independently and denoted by $n_{.1}$ items or individuals selected in both samples are recorded and denoted by $n_{11}$. The sizes of samples drawn are not necessarily at bay. Supplementary Immunization Activities (SIAs) are vaccination campaigns conducted at National and Subnational scale to boost immunity against Vaccine Preventable Diseases (VPD) such as polio and Lot Quality Assurance Survey (LQAS) was introduced to assess the coverage of the immunization activities with the view to get quick idea of what the coverage is so as to decide whether to accept or reject the lot(s) on the basis of a predetermine number of acceptable defects (unvaccinated). Since the size of the first sample is inordinately different to the second sample in LQAS, a disproportionate capture-recapture (C-R) model was developed to address the disparity, estimate SIAs coverage and enhance precision of estimate classification.

Keywords: supplementary immunization activities, lot quality assurance survey, capture-recapture (C-R) models, disproportionality, global polio eradication initiative

## 1. Introduction

Two sample capture-recapture (C-R) techniques are used to evaluate and approximate the size of a population using individuals or items selected from two samples of almost equal magnitude. A special type of two sample C-R methods with disproportionality between the sizes of the two samples is obtained as exemplified in the biggest internationally organized public health project, the Global Polio eradication Initiative (GPEI) which is lunched in 1988 (Tebbens et al., 2010). The improvement in the quality of life from the paralysis and deaths that would be avoided and money that would have been used for procurement of vaccines deployed to other areas of lives was the anticipated relevance of the GPEI (Thompson et al., 2006). Sangrujee et al. (2004) estimated the gains accruable from postpolio certification and found out that the budgets on the vaccine per dose and targeted number factors of the global costs of post certification polio vaccination.

When National Immunization Plus Days are conducted, primary supervision is vital for problem identification in planning and reporting, observing particular areas of inadequate coverage, and forecasting the tendency of the spread of disease. The use of supervisory tools before, during and after National Immunization

[^0]Plus Days (NIPD) is hampered because entrenching and adopting reliable techniques to generate data can be improved in the buildup and implementation of humongous national activities in addition to unreliable regular monitoring data which show appreciable level of coverage in almost all areas, including those with current cases of virus circulation. To mitigate this problem, LQAS was adopted because data collected is quickly and easily interpreted (Brown et al., 2014).

LQAS which was initially developed for industrial quality control, has been applied to health surveys. It is a quick sampling technique deployed to evaluate the viability of immunization coverage sequel to SIAs in a settlement that has been determined ahead of time using small sample size. It is particularly used in areas with risk or polio dominated area to execute corrective action such as mop-up in areas identified to be weak in coverage (Manual, 2012; Jutand \& Salamon, 2000; Olives, 2011). With a small investment, this method enables programme directors to identify rapidly the health facilities with below standard services and therefore requiring special attention (Valadez, 1991).

As a statistically dependable tool for supervising polio immunization, LQAS has proven its relevance in determining campaign quality. Information supplied by LQAS in determining the quality of SIAs coverage has helped to distinguish the areas that seriously in need of intervention. More so, the capacity of

GPEI to track the patterns of immunization quality overtime can be hinged on LQAS, an improvement on SIAs pre-implementation of LQAS (Brown et al., 2014).

Some of the limitations of CLQAS as enunciated in (Manual, 2012) are: (i) if the lot is too enormous and heterogenous in coverage, LQAS may not give the coverage of the entirety of the lot, thereby diffusing its reliability across the entire lot (e.g. ward); (ii) LQAS doesn't give us the point estimate of the coverage but classification of SIA coverage; and (iii) there is a tendency for misclassification due to the relatively small sample size and clustering approach. In fact, statistical error can be very high in lot where coverage varies greatly between clusters.

Capture-Recapture (C-R) techniques are used for assessing the size of a population based on ratio of tagged to untagged individual (Amstrup \& Mcdonald, 2010). Mingoti and Caiaffa (2006), noted that C-R can be used to estimate the size of unknown finite population size. Pollock (1981), affirmed that the population under review can be sampled more than a time. At every occasion, every untagged individual caught is specially tagged; previously tagged individuals have their capture history recorded and returned into the population. Therefore, by the time the study is concluded, the researcher has the comprehensive history of each individual handled.

In using LQAS, subsamples of the population (lots) are either accepted or rejected based on the number of defects in a random sample $(N)$ of a given lot. Should the number of defects is higher than decision value (d), the lot is rejected and remedial measures recommended in the lot; should the number of defects is equal or less than d, the lot is accepted (Pezzoli \& Kim, 2013). Since the variableness in the percentage of children immunized among clusters within a lot has remarkable relevance on the remarkable impact on the coverage estimates, the probability of error is increased by high variability thereby weakening the strength of the "pass/fail" determination (Okayasu et al., 2014). To this end, overestimation of immunization coverage may leave populations at risk, whilst underestimation can lead to unnecessary catch-up campaigns (Alberti et al., 2008). Additionally, there were instances where the Wild Polio Virus (WPV) were recorded in lots where the LQAS coverage were estimated to have been high. As a result of the high estimate, program activities were relapsed and the virus was spreading. To this effect, reliance on LQAS coverage alone might not in all cases give a true reflection of the reality on ground, hence the need to incorporate estimated population size. Intrinsic heterogeneity in C-R techniques is reduced by stratification (Sutherland \& Schwartz, 2005). Stratification in LQAS would address the effect of intrinsic heterogeneity in C-R techniques and the estimated population size would address the frailty of LQAS due to small sample size. Therefore, C-R techniques in alliance with CLQAS (where lots are classified into clusters) would provide a more precise insight of the coverage estimate, hence the need for this study.

This work is aimed at developing an effective model that could be used to estimate SIAs coverage with a view to enhance the precision of the estimate classification by developing a model for disproportionate two sample capture recapture.

## 2. Literature Review

### 2.1. Immunization coverage surveys

Siddiqi et. al. (2021) studied how powerful, vaccine data are generated via Electronic Immunization Registers (EIR) are used to supervise vaccination workers and ensuring that remedial
measures are strategically targeted at communities identified as chronically missed. They suggested the importance of generating and using quality data for evidence-based decision making to overcome the obstacles inherent in immunization system in order to attain the Sustainable Development Goal (SDGs) of ensuring healthy lives and well-being for all persons at all ages, especially for newborn and children under the age of 5 .

Abbott et al. (2021) showed how Measurement and Improvement (M\&I) strategy has helped to mitigate the variableness across Immunization Information System and strengthen immunization data in Immunization Information System (IIS) which is more comprehensive, reliable and can be used with certain degree of certainty that is of particular relevance in actualizing Sustainable Development Goal targeted at enhancing healthy lives and elevating well-being for all age groups via robust immunization system.

Pincipal target of immunization programmes is to assuage the frequency of occurrence of vaccine preventable of diseases (VPDs) by reaching high levels of routine immunization coverage with viable vaccines (Uwaibi \& Omozuwa, 2020). As one of the countries accounting for $62 \%$ of under and unvaccinated children worldwide, Nigeria needs to strengthen its immunization system (Olaniyan et al., 2021). The major attention of the health-related SDGs number three is universal health coverage (UHC), encompassing access to secured, robust, excellent, and affordable essential medicines and vaccines. However, the problems to realizing UHC are enormous, particularly with increases reliance on the health sector whose budget is either stagnant or plummeting (Chopra et al., 2020).

### 2.2. Underlying assumptions

The assumptions required for incorporating the number of units selected in both samples and the number of units selected in just one sample to evaluate the number of units not selected in both samples, therefore, providing estimate of the entire population magnitude, $N$, can be itemized in a number of ways, but the substratum is unpacked as following (International Working Group for Disease Monitoring and Forecasting, 1995):
i. Closure: the population under study is closed that is, the population is unaffected by change in birth, death or migration during the study period.
ii. Perfect matching: subjects captured in one sampling unit can be precisely paired to another sampling unit with no variation (no unpair, no loss of tag, etc.).
iii. Homogeneity: within each source, all subjects have equal chance of being selected (that is the "catchability" is equal for all subjects).
iv. Independence: the two sources are independent, that is, the likelihood of a subject being selected in one sampling unit is independent of subject selected from other sampling units whether the unit was captured in the other source.

### 2.3. Capture recapture techniques

To improve the Petersen estimates when heterogeneity is deemed to affect the estimates, Sekar and Deming (1949) employed stratification to evaluate the rate of birth and death using two lists. Pollock (1976) explicitly highlighted a step by step approach to building models and the importance of assumptions in the building of such models. He used the trap response models to accentuate the problem of non-identifiability of the parameter $N$. He found that $N$ could not be estimated unless
the often-unrealistic assumption that the probability of capture of the unmarked animal is constant for both samples.

Manning and Goldberg (2010) designed a method to build spatial explicit capture-recapture selection histories from sites of untagged species for evaluating population magnitude with conventional C-R techniques. They applied the technique to data from point coordinate capture-recapture sampling method for more species with the probability of detecting error.

Focusing on the model formulation rather than on the estimation methods (which include inverse prediction, maximum likelihood and Bayesian methods) in a non-technical way, omitting much of the algebraic detail, Borchers (2012) reviewed capture recapture models that do include an explicit spatial component. He observed in an attempt to synthesize these models, that starting with circular plot survey models and moving through conventional distance sampling models, with and without measurement errors, through mark-recapture distance sampling (MRDS) model; concluded that spatial explicit capture-recapture (SCR) models can be viewed as an endpoint of a series of spatial sampling models.

Jibasen et al. (2012) presented a robust capture-recapture model for estimating the size of elusive epidemiologic events. They compared a proposed estimator $\widehat{N}_{c}$ the Petersen estimator $\widehat{N}_{s}$ and another estimator $\widehat{N}_{0}$ using the Akaike Information Criterion (AIC) and the Mean Absolute Deviation (MAD) through simulation studies. The study shows that both AIC and MAD revealed that $\widehat{N}_{c}$ is a better and robust estimator. The research further discovered that $\widehat{N}_{s}$ under estimates the total elusive population $N, \widehat{N}_{0}$ over estimates $N$ while $\widehat{N}_{c}$ was always consistent and performs better than the other two and hence, recommended that the proposed estimator $\widehat{N}_{c}$ be used for estimating dual system elusive events.

Jibasen and Adams (2013) proposed an efficient two sample capture-recapture model $\left(M_{\mathrm{a}}\right)$ with high recaptures and compared it with the existing models such as the model of no factor effect $\left(M_{\mathrm{o}}\right)$, behavioral response model $\left(M_{\mathrm{b}}\right)$ and the Petersen model $\left(M_{\mathrm{s}}\right)$, using simulated data. They found that the proposed model provides a better estimator of the population size than the existing ones when the recapture is high, that is, in situations where individuals respond positively to capture, and also found that the Petersen model provides a better estimate of the population size when the observations follow a hyper-geometric distribution.

Sekar and Deming (1949), Ahlo (1990), Chao et al. (2008); Chao et al. (2001), and Royle and Converse (2014) use stratification to address the biasness in Petersen estimator under population heterogeneity. Manning and Goldberg (2010); and Borchers (2012) reviewed C-R models that include explicit spatial components for estimating population size. Chao et al. (2001), Chao et al. (2008); Pollock (1976), and Clavel et al. (2008) presented an intuitive interpretation for independence between capture sample and recapture sample while "trap happy" and "trap shy" were buttressed with explicit exposition on elusive event by Jibasen et al. (2012).

Apart from Okayasu et al. (2014) who conducted a pilot evaluation in four LGAs in Nigeria with an expanded LQAS sample size 16 clusters instead of the standard 6 clusters of 10 subjects each and found out that improvement in precision was deemed insufficient to warrant the effort, most literatures reviewed on LQAS were more emphatic on its application rather than its formation. They also noted that since variability in the proportion of children vaccinated among clusters within a lot has a remarkable impact on the coverage estimates, the probability of error is increased by high variability thereby compromising the robustness of the "pass/fail" determination. This may lead to
overestimation of vaccination coverage which may leave populations at risk or underestimation which can lead to unnecessary catch-up campaigns (Alberti et al., 2008).

This work proposes C-R models that takes into consideration the disproportionality between the first and the second sample sizes in two sample capture recaptures.

## 3. Methodology

### 3.1. Model direction

This work focused on two-sample C-R model where the first sample typically is the enumeration of the target population (i.e. children under the age of 5 years that were immunized during SIAs) while the second sample is a small fraction of the first. During SIAs, vaccination teams move from house-to-house, immunizing children under the age of 5 years and finger marking them as indication that they have been immunized. Two days after the immunization campaign, independent surveyors are deployed to take sample of 60 eligible children from selected lots (wards) and coverage based on the principle of LQAS is reached by considering children that have been finger marked vis-à-vis those not finger marked. This is a topology of two-sample C-R technique. While the usual two-sample C-R methods considered two independent samples of almost the same size, this research is looking at a situation where the two samples sizes are greatly disproportionate.

### 3.2. The proposed model ( $M_{p}$ )

Disproportionate two sample Capture Recapture, was derived from the general (unrestricted) two sample capture recapture model. The general two-sample C-R model is given as:

$$
\begin{gather*}
P\left(n_{1 .}, n_{1 .}, n_{11}\right)=\binom{N}{n_{1 .}}\binom{n_{1}}{n_{11}}\binom{N-n_{1 .}}{n_{.1}-n_{11}} P_{1 .}^{n_{1 .}}\left(1-P_{1 .}\right)^{N-n_{1} . *} \\
C^{n_{11}}(1-C)^{n_{1}-n_{11}} P_{.1}^{n_{1}-n_{11}}\left(1-P_{.1}\right)^{N-n_{1 .}-n_{1}+n_{11}} \tag{1}
\end{gather*}
$$

Where,
$n_{1 .}=$ number of captures in the first sample
$n_{.1}=$ number of captures in the second sample
$n_{11}=$ number of captures in both sample
$P_{1 .}=$ Captures probability in the first sample
$P_{.1}=$ Captures probability in the second sample
$C=$ Capture probability in both samples
Also note that robustness when conditions are altered by relapsing and constraining at least a parameter results in the following: when,
i. $P_{1 .}=C$, while $P_{.1}$ is unaffected, Petersen Model $M_{s}$ ensue.
ii. $P_{.1}=C$, while $P_{1 \text {. is }}$ unaffected, Effective Model for High Recaptures $M_{a}$ ensue.
iii. $P_{.1}=P_{1 .}$, while $C$ is unaffected, Behavioral Model $M_{b}$ ensue.
iv. $P_{.1}=P_{1 .}=C$, No Effect Model (Restricted Model) $M_{o}$ ensue.

In SIAs, the number of children immunized and the number of children sampled during LQAS represent the first and second sample respectively.

Since the number of children sampled during LQAS is a small proportion of number of children immunized during House to House campaign, it is important that a suitable CR model be developed to address the issue of gross disproportionality between the first
and the second sample as shown in Figure 1. $f\left(n_{11}\right)$ as depicted in equation (5) is introduced as a replacement to the second sample distribution into the general model to curb the parity between the two samples.

Figure 1
Venn diagram showing disproportionate two sample capture recapture

### 3.3. Assumptions of the proposed C-R models

Assumptions for the proposed dipropionate capture recapture model are as follows:
i. Let $n_{1 .}$ and $n_{1}$ be the observed sample sizes of the first and second samples respectively as depicted in Figure 2.

Figure 2
Venn diagram showing first sample and second sample observed

ii. Let $E_{1}$. and $E_{.1}$ be the expected sample sizes of the first and second samples respectively.
iii. The expected sample sizes of both samples are approximately the equal $\left(E_{1 .}=E_{1 .}\right)$ as shown in Figure 3.

Figure 3
Venn diagram showing expected sample sizes of the first and second samples

The expected and observed sample sizes of the first sample are approximately the same $\left(E_{1 .}=n_{1 .}\right)$ as demonstrated in Figure 4.

Figure 4
Venn diagram showing equal observed and expected sizes of the first sample

iv. The subset and superset of the second sample have the same interception with the first sample.
v. Let:

Combination of the observed subset

$$
\begin{equation*}
C m_{s u b 1}=\binom{n_{1 .}}{n_{.1}} \tag{2}
\end{equation*}
$$

Combination of the unobserved subset

$$
\begin{equation*}
C m_{\text {sub } 2}=\binom{N-2 n_{1 .}}{n_{1 .}-n_{.1}-n_{11}} \tag{3}
\end{equation*}
$$

Combination of the expected superset

$$
\begin{equation*}
C m_{\text {sup }}=\binom{N-n_{1 .}}{n_{1 .}-n_{11}} \tag{4}
\end{equation*}
$$

Let $\quad P_{\text {sup }}=\binom{N-n_{1 .}}{n_{.1}-n_{11}} P_{.1}^{n_{1}-n_{11}}\left(1-P_{.1}\right)^{N-n_{1}-n_{1}+n_{11}} \quad$ be the probability of the expected superset of the second sample from whence the undercount could be adjusted. By merging equations (2), (3) and (4), we get a hypergeometric probability, denoted by $f\left(n_{1}\right)$, thus:

$$
\begin{equation*}
f\left(n_{.1}\right)=\frac{\binom{n_{1 .}}{n_{.1}}\binom{N-2 n_{1 .}}{n_{1 .}-n_{.1}-n_{11}}}{\binom{N-n_{1 .}}{n_{1 .}-n_{11}}} \tag{5}
\end{equation*}
$$

Therefore, equation (1) becomes:

$$
\begin{align*}
& P\left(n_{1 .}, n_{1 .}, n_{11}\right)= \\
& \binom{N}{n_{1 .}} P_{1_{1 .} .\left(1-P_{1 .}\right)^{N-n_{1}}}\binom{n_{11}}{n_{11}} C^{n_{11}}(1-C)^{n_{1 .}-n_{11}} * \frac{\binom{n_{1 .}}{n_{1}}\binom{N-2 n_{1 .}}{n_{1 .}-n_{1}-n_{11}}}{\binom{N-n_{1 .}}{n_{1 .}-n_{11}}} \tag{6}
\end{align*}
$$

As the binomial distribution of the second sample which is written thus:

$$
\binom{N-n_{1 .}}{n_{.1}-n_{11}} P_{.1}^{n_{1}-n_{11}}\left(1-P_{.1}\right)^{N-n_{1 .}-n_{.1}+n_{11}}
$$

becomes a hypergeometric distribution:

$$
\frac{\binom{n_{1 .}}{n_{.1}}\binom{N-2 n_{1 .}}{n_{1 .}-n_{.1}-n_{11}}}{\binom{N-n_{1 .}}{n_{1 .}-n_{11}}}
$$

Using maximum likelihood estimation method, equation (6) yields maximum likelihood estimator (MLE) as:

$$
\begin{gather*}
\hat{P}_{1 .}=\frac{n_{1 .}}{\widehat{N}}  \tag{7}\\
\hat{C}=\frac{n_{11}}{n_{1 .}}  \tag{8}\\
\frac{L(N)}{L(N-1)}=1 \Rightarrow \frac{\widehat{N}}{\widehat{N}-n_{1 .}} * \frac{\widehat{N}-2 n_{1 .}}{\widehat{N}-3 n_{1 .}+n_{11}+n_{11}} * \frac{\widehat{N}-2 n_{1 .}+n_{11}}{\widehat{N}-n_{1 .}} *\left(1-\hat{P}_{1 .}\right)=1 \tag{9}
\end{gather*}
$$

Substituting equation (8) in equation (9) gives us the appropriate Maximum Likelihood estimator of $N$, thus:

$$
\begin{equation*}
\widehat{N}_{p}=\frac{n_{1 .}\left(n_{1 .}+n_{.1}-n_{11}\right)}{n_{.1}} \tag{10}
\end{equation*}
$$

Using Delta Method as expounded by Jibasen (2011), where the variance $\operatorname{Vf}(x)$ of a function of $x$ is estimated as:

$$
\operatorname{Varf}(x)=\left(\frac{\partial f}{\partial x}\right)_{E}^{2} \operatorname{var}(x)
$$

Such that ()$_{E}$ represent replacement of the expected value for $x$ in the differentiation of the bracket while $\operatorname{var}(x)$ represents the variance of $x$.

Therefore, the variance of $M_{P}$ is given by:

$$
\begin{gathered}
\operatorname{var}\left(\widehat{N}_{P}\right)=\operatorname{var}\left(\frac{n_{1 .}\left(n_{1 .}+n_{.1}-n_{11}\right)}{n_{.1}}\right) \\
\operatorname{var}\left(\widehat{N}_{P}\right)=\operatorname{var}\left(\frac{\left(n_{1 .}^{2}+n_{1 . n_{.1}}\right)}{n_{.1}}-\frac{n_{1 . n_{11}}}{n_{.1}}\right) \\
\operatorname{var}\left(\widehat{N}_{P}\right)=\operatorname{var}\left(-\frac{n_{1 . n_{11}}}{n_{.1}}\right) \\
\operatorname{var}\left(\widehat{N}_{P}\right)=\left(-\frac{n_{1 .}}{n_{.1}}\right)^{2} \operatorname{var}\left(n_{11}\right) \\
\operatorname{var}\left(\widehat{N}_{P}\right)=\frac{n_{1 .}^{2}}{n_{.1}^{2}} \operatorname{var}\left(\frac{\partial f\left(n_{11}\right)}{\partial n_{11}}\right)_{E}^{2} \operatorname{var}\left(n_{11}\right) \\
\operatorname{var}\left(\widehat{N}_{P}\right)=\frac{n_{1 .}^{2}}{n_{.1}^{2}}\left(\widehat{N}_{P} p_{1 ;} q_{1 .}\right) \\
\operatorname{var}\left(\widehat{N}_{P}\right)=\frac{n_{1 .}^{2}}{n_{.1}^{2}} \widehat{N}_{P}\left(\frac{n_{1 .}}{\widehat{N}_{P}}\right)\left(\frac{\widehat{N}_{P}-n_{1 .}}{\widehat{N}_{P}}\right)
\end{gathered}
$$

$$
\begin{equation*}
\operatorname{var}\left(\widehat{N}_{P}\right)=\frac{n_{1 .}^{3}}{n_{.1}^{2}}\left(\frac{\widehat{N}_{P}-n_{1 .}}{\widehat{N}_{P}}\right) \tag{11}
\end{equation*}
$$

### 3.4. Model selection criteria

Comparing the proposed model with existing models, Mean Absolute Deviation (MAD) and Akaike Information Criteria (AIC) were used.

Mean Absolute Deviation (MAD) in case of simulation and is given as:

$$
\begin{equation*}
M A D=\frac{|N-\widehat{N}|}{n} \tag{12}
\end{equation*}
$$

Unrealistically simple assumptions are made which lead to high bias, poor prediction, and missed opportunities for insight when choosing a model with too few parameters. Such models lack the flexibility to explain the sample or the population well. A model with too many parameters can fit the observed data very well, but be too closely tailored to it. Such models may generalize poorly. Penalizedlikelihood information criteria, such as Akaike's Information Criterion (AIC) and the Bayesian Information Criterion (BIC), are widely used for model selection (Dziak et al., 2020).

The AIC is computed as follows:

$$
\begin{equation*}
A I C=-2 \log L\left(\theta^{\wedge}\right)+2 k \tag{13}
\end{equation*}
$$

where
$\theta=$ the set (vector) of model parameters
$L\left(\theta^{\wedge}\right)=$ the likelihood of the candidate model given the data when evaluated at the maximum likelihood estimate of $\theta$
$k=$ the number of estimated parameters in the candidate model
There is no problem of subjectively specifying an arbitrary significance level to test the models, and comparisons are not restricted to two models which are nested or hierarchically ordered. It is easy to calculate AIC once the maximum likelihood estimators of the parameters of a model are determined. A model with a minimum value of AIC is chosen to be the best fitting model among several competing models (Takane \& Bozdogan, 1987).

The BIC is computed as follows:

$$
\begin{equation*}
B I C=-2 \log L\left(\theta^{\wedge}\right)+k \log (n) \tag{14}
\end{equation*}
$$

where
$\theta=$ the set (vector) of model parameters
$L\left(\theta^{\wedge}\right)=$ the likelihood of the candidate model given the data when evaluated at the maximum likelihood estimate of $\theta$
$k=$ the number of estimated parameters in the candidate model
$n=$ the sample sizes

When $n$ should be used in the context of mark-recapture is ambiguous. While some are advocating that $n$ is the total number of recorded individuals in the population, others are of the opinion that it should instead be the number of releases, excluding those released from the last sample. AIC is preferable to avoid such inconsistency (Burnham et al., 2011).

Since we are dealing with disproportionality between the first and the second samples whose sizes differ greatly, attempt to consistently estimate the dimension model which requires that the sample size is very large, in model selection we focused more on the distance rather than on dimension of the true model. To this end, the suggestion by Anderson and Burnham (1999) which recommends the use of criteria that are based on Kullback-Leibler information in biological sciences was adopted. AIC is better in situations when a false negative finding would be considered more misleading than a false positive, and BIC is better where false positive is as misleading as, or more misleading than a false negative (Acquah, 2010). In capture recapture model selection, AIC performs slightly better than the BIC methods, which tend to select simpler models (Hook, \& Regal, 2000). The usually preferred model selection method in capture recapture studies is the AIC (Zwane et al., 2004).

The Akaike Information Criteria (AIC) used in this work was proposed by Sanni and Jolayemi as cited in Jibasen and Adams (2013) as:

$$
\begin{equation*}
A I C=-\beta \sum_{i_{0}}^{c_{0}} \sum_{i_{1}}^{c_{1}} n\left(i_{0}, i_{1}\right) \log _{e} \frac{n\left(i_{0}, .\right) n\left(., i_{1}\right)}{\widehat{N}^{2}}+2\left(c_{0}+c_{1}-2\right) \tag{15}
\end{equation*}
$$

Where, $c_{0}$ and $c_{1}$ are the dimensions of the contingency table, $\beta$ is equal to 2 just like it is in the classical, or identified as $\operatorname{Abs}(N-\widehat{N})$ in case of simulation, $n$ is the number of observations, $N$ is the hypothesized (in case of simulation) and $\widehat{N}$ is the estimated population size. Taking into account that population size estimate may be very sensitive if certain cells are null or very sparse, using log-linear capture-recapture methods Hooks and Regal (1997) suggested that the use of AIC in model selection appears to be preferrable over its BIC counterpart.

### 3.5. Simulation studies

The hypothesized population size $N$ as well as the first sample size $n_{1 .}$ and the second sample size $n_{.1}$ which represent house to house immunization during immunization plus days and LQAS coverages respectively were used to simulate the size of capture in both
samples using the hypergeometric setting (Jibasen et al., 2012), thus:

$$
P\left(n_{11}\right)=\left\{\begin{array}{cl}
\frac{\binom{n_{1 .}}{n_{11}}\binom{n_{.1}}{n_{01}}}{\binom{N}{n_{11}}}, & n_{11}=\max \left(0, n_{.1}-n_{1,}\right) \text { to } \min \left(n_{.1}, n_{1,}\right)  \tag{16}\\
& 0, \text { otherwise }
\end{array}\right.
$$

Simulation scheme was repeated ten times (it could be more) for every hypothesized first, second and population sizes and population sizes for $N_{o}, N_{s}, N_{b}, N_{a}$ (see Jibasen \& Adams, 2013) and $N_{p}$ were estimated.

$$
\begin{equation*}
\widehat{N}_{0}=\frac{n^{2}}{4 n_{11}} \tag{17}
\end{equation*}
$$

Where, $n=n_{1 .}+n_{.1}$

$$
\begin{gather*}
\widehat{N}_{s}=\frac{n_{1 .} n_{1}}{n_{11}}  \tag{18}\\
\widehat{N}_{b}=\frac{n_{1 .}^{2}}{n_{1 .}-\left(n_{.1}-n_{11}\right)}  \tag{19}\\
\widehat{N}_{a}=\frac{n_{11}\left(n_{.1}-n_{11}\right)+\left(n_{1 .}+n_{11}\right) n_{1 .}}{2 n_{11}} \tag{20}
\end{gather*}
$$

## 4. Results and Discussion

Tables $1-10$ show comparison between the proposed disproportional C-R model and some existing C-R models using simulated data, AIC and MAD. Results of simulated data for different hypothesized values of $N, n_{1 .}$ and $n_{.1}$ are presented in this session, the simulated data were used to compute estimated population size, AIC values and MAD using the five models, these are $M_{\mathrm{o}}, M_{\mathrm{s}}, M_{\mathrm{b}}, M_{\mathrm{a}}$, and $M_{\mathrm{p}}$ which are No factor effect model, Petersen model, Behavioral model, High recapture model and the proposed model. Each iteration is a complete set of simulation as depicted in Tables 1-10.

Table 1
Ten simulated data sets: $\boldsymbol{N}=\mathbf{1 0 0}, \boldsymbol{n}_{1 .}=\mathbf{5 0}$ and $\boldsymbol{n}_{.1}=\mathbf{3 0}$

| Simulation |  | Estimated population |  |  |  |  | AIC |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Iteration | $n_{11}$ | $\widehat{N}_{o}$ | $\widehat{N}_{s}$ | $\widehat{N}_{b}$ | $\widehat{N}_{a}$ | $\widehat{N}_{p}$ | $M_{o}$ | $M_{s}$ | $M_{b}$ | $M_{a}$ | $M_{p}$ |
| 1 | 20 | 32,000 | 75 | 63 | 37,000 | 100 | 85,711 | 11 | 11 | 101,288 | 4 |
| 2 | 18 | 28,800 | 83 | 66 | 32,544 | 103 | 68,314 | 9 | 10 | 78,653 | 5 |
| 3 | 20 | 32,000 | 75 | 63 | 37,000 | 100 | 85,711 | 11 | 11 | 101,288 | 4 |
| 4 | 19 | 30,400 | 79 | 64 | 34,761 | 102 | 76,752 | 10 | 11 | 89,562 | 5 |
| 5 | 21 | 33,600 | 71 | 61 | 39,260 | 98 | 95,197 | 11 | 11 | 113,839 | 5 |
| 6 | 18 | 28,800 | 83 | 66 | 32,544 | 103 | 68,314 | 9 | 10 | 78,653 | 5 |
| 7 | 19 | 30,400 | 79 | 64 | 34,761 | 102 | 76,752 | 10 | 11 | 89,562 | 5 |
| 8 | 17 | 27,200 | 88 | 68 | 30,354 | 105 | 60,396 | 7 | 10 | 68,552 | 6 |
| 9 | 21 | 33,600 | 71 | 61 | 39,260 | 98 | 95,197 | 11 | 11 | 113,839 | 5 |
| 10 | 20 | 32,000 | 75 | 63 | 37,000 | 100 | 85,711 | 11 | 11 | 101,288 | 4 |
| MAD |  | 30,780 | 22 | 36 | 35,348 | 2 |  |  |  |  |  |

Table 1 shows that the proposed model $M_{\mathrm{p}}$ is better than any other model in AIC, MAD and its estimation of the population size.

Table 2
Ten simulated data sets: $N=100, n_{1 .}=60$ and $n_{.1}=45$

| Simulation |  | Estimated population |  |  |  |  | AIC |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Iteration | $n_{11}$ | $\widehat{N}_{\text {o }}$ | $\widehat{N}_{\text {s }}$ | $\widehat{N}_{\text {b }}$ | $\widehat{N}_{\mathrm{a}}$ | $\widehat{N}_{\mathrm{p}}$ | $M_{o}$ | $M_{s}$ | $M_{b}$ | $M_{a}$ | $M_{p}$ |
| 1 | 30 | 82,688 | 90 | 80 | 87,750 | 100 | 365,321 | 7 | 9 | 390,839 | 4 |
| 2 | 26 | 71,663 | 104 | 88 | 73,502 | 105 | 269,021 | 5 | 7 | 276,904 | 6 |
| 3 | 27 | 74,419 | 100 | 86 | 77,031 | 104 | 291,643 | 4 | 8 | 303,327 | 5 |
| 4 | 27 | 74,419 | 100 | 86 | 77,031 | 104 | 291,643 | 4 | 8 | 303,327 | 5 |
| 5 | 30 | 82,688 | 90 | 80 | 87,750 | 100 | 365,321 |  | 9 | 390,839 | 4 |
| 6 | 27 | 74,419 | 100 | 86 | 77,031 | 104 | 291,643 | 4 | 8 | 303,327 | 5 |
| 7 | 24 | 66,150 | 113 | 92 | 66,528 | 108 | 226,661 | 9 | 6 | 228,140 | 7 |
| 8 | 22 | 60,638 | 123 | 97 | 59,686 | 111 | 188,115 | 13 | 5 | 184,744 | 8 |
| 9 | 27 | 74,419 | 100 | 86 | 77,031 | 104 | 291,643 | 4 | 8 | 303,327 | 5 |
| 10 | 28 | 77,175 | 96 | 84 | 80,584 | 103 | 315,230 | 5 | 8 | 331,121 | 5 |
| MAD |  | 73,768 | 6 | 14 | 76,292 | 4 |  |  |  |  |  |

Table 2 clearly shows that while $M_{\mathrm{o}}$ and $M_{\mathrm{a}}$ models performing poorly, $M_{\mathrm{p}}$ performed excellently well with the lowest AIC and MAD values. And much better estimation of the population size.

Table 3
Ten simulated data sets: $N=200, n_{1 .}=90$ and $\boldsymbol{n}_{.1}=60$

| Simulation |  | Estimated population |  |  |  |  | AIC |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Iteration | $n_{11}$ | $\widehat{N}_{o}$ | $\widehat{N}_{s}$ | $\widehat{N}_{b}$ | $\widehat{N}_{a}$ | $\widehat{N}_{p}$ | $M_{o}$ | $M_{s}$ | $M_{b}$ | $M_{a}$ | $M_{p}$ |
| 1 | 41 | 230,625 | 132 | 114 | 257,665 | 164 | 1,521,317 | 37 | 35 | 1,723,244 | 28 |
| 2 | 46 | 258,750 | 117 | 107 | 296,332 | 156 | 1,942,546 | 40 | 36 | 2,261,856 | 34 |
| 3 | 36 | 202,500 | 150 | 123 | 219,672 | 171 | 1,153,806 | 30 | 32 | 1,264,607 | 22 |
| 4 | 46 | 258,750 | 117 | 107 | 296,332 | 156 | 1,942,546 | 40 | 36 | 2,261,856 | 34 |
| 5 | 40 | 225,000 | 135 | 116 | 250,000 | 165 | 1,443,540 | 36 | 35 | 1,625,131 | 27 |
| 6 | 34 | 191,250 | 159 | 127 | 204,748 | 174 | 1,021,681 | 26 | 31 | 1,103,351 | 19 |
| 7 | 44 | 247,500 | 123 | 109 | 280,808 | 159 | 1,767,565 | 39 | 36 | 2,036,810 | 32 |
| 8 | 36 | 202,500 | 150 | 123 | 219,672 | 171 | 1,153,806 | 30 | 32 | 1,264,607 | 22 |
| 9 | 44 | 247,500 | 123 | 109 | 280,808 | 159 | 1,767,565 | 39 | 36 | 2,036,810 | 32 |
| 10 | 46 | 258,750 | 117 | 107 | 296,332 | 156 | 1,942,546 | 40 | 36 | 2,261,856 | 34 |
| MAD |  | 232,113 | 68 | 86 | 260,037 | 37 |  |  |  |  |  |

Table 3 clearly shows that $M_{\mathrm{p}}$ performed better than all the model under consideration following closely by $M_{\mathrm{s}}$ model.

Table 4
Ten simulated data sets: $N=300, \boldsymbol{n}_{1 .}=90$ and $\boldsymbol{n}_{.1}=\mathbf{3 5}$

| Simulation |  | Estimated population |  |  |  |  | AIC |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Iteration | $n_{11}$ | $\widehat{N}_{o}$ | $\widehat{N}_{s}$ | $\widehat{N}_{b}$ | $\widehat{N}_{a}$ | $\widehat{N}_{p}$ | $M_{o}$ | $M_{s}$ | $M_{b}$ | $M_{a}$ | $M_{p}$ |
| 1 | 29 | 113,281 | 109 | 96 | 157,818 | 247 | 498684 | 77 | 67 | 725,554 | 50 |
| 2 | 27 | 105,469 | 117 | 99 | 145,071 | 252 | 428129 | 76 | 65 | 614,267 | 43 |
| 3 | 30 | 117,188 | 105 | 95 | 164,250 | 244 | 536093 | 77 | 68 | 785,151 | 53 |
| 4 | 26 | 101,563 | 121 | 100 | 138,762 | 255 | 394973 | 75 | 63 | 562,537 | 40 |
| 5 | 31 | 121,094 | 102 | 94 | 170,717 | 242 | 574931 | 76 | 69 | 847,405 | 57 |
| 6 | 30 | 117,188 | 105 | 95 | 164,250 | 244 | 536093 | 77 | 68 | 785,151 | 53 |
| 7 | 28 | 109,375 | 113 | 98 | 151,424 | 249 | 462698 | 77 | 66 | 668,599 | 46 |
| 8 | 27 | 105,469 | 117 | 99 | 145,071 | 252 | 428129 | 76 | 65 | 614,267 | 43 |
| 9 | 20 | 78,125 | 158 | 108 | 102,000 | 270 | 225338 | 63 | 54 | 305,313 | 23 |
| 10 | 24 | 93,750 | 131 | 103 | 126,288 | 260 | 332872 | 73 | 61 | 466,789 | 34 |
| MAD |  | 105,950 | 182 | 201 | 146,265 | 49 |  |  |  |  |  |

Table 4 vividly portray $M_{\mathrm{p}}$ is the best model in both AIC and MAD values as well as estimates of the population.

Table 5
Ten simulated data sets: $N=300, n_{1 .}=150$ and $\boldsymbol{n}_{.1}=90$

| Simulation |  | Estimated population |  |  |  |  | AIC |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Iteration | $n_{11}$ | $\widehat{N}_{o}$ | $\widehat{N}_{s}$ | $\widehat{N}_{b}$ | $\widehat{N}_{a}$ | $\widehat{N}_{p}$ | $M_{o}$ | $M_{s}$ | $M_{b}$ | $M_{a}$ | $M_{p}$ |
| 1 | 65 | 936,000 | 208 | 180 | 1,100,938 | 292 | 10,940,576 | 74 | 72 | 13,101,316 | 14 |
| 2 | 60 | 864,000 | 225 | 188 | 999,000 | 300 | 9,238,940 | 63 | 69 | 10,857,017 | 4 |
| 3 | 60 | 864,000 | 225 | 188 | 999,000 | 300 | 9,238,940 | 63 | 69 | 10,857,017 | 4 |
| 4 | 63 | 907,200 | 214 | 183 | 1,060,007 | 295 | 10,241,851 | 70 | 71 | 12,175,385 | 10 |
| 5 | 56 | 806,400 | 241 | 194 | 918,512 | 307 | 7,985,655 | 52 | 65 | 9,230,167 | 11 |
| 6 | 53 | 763,200 | 255 | 199 | 858,892 | 312 | 7,108,291 | 42 | 62 | 8,107,397 | 16 |
| 7 | 61 | 878,400 | 221 | 186 | 1,019,280 | 298 | 9,567,232 | 66 | 69 | 11,287,086 | 6 |
| 8 | 65 | 936,000 | 208 | 180 | 1,100,938 | 292 | 10,940,576 | 74 | 72 | 13,101,316 | 14 |
| 9 | 60 | 864,000 | 225 | 188 | 999,000 | 300 | 9,238,940 | 63 | 69 | 10,857,017 | 4 |
| $10$ | 54 | 777,600 | 250 | 197 | 878,688 | 310 | 7,394,805 | 45 | 63 | 8,472,442 | 15 |
| MAD |  | 859,380 | 73 | 112 | 993,125 | 5 |  |  |  |  |  |

Table 5 depicts $M_{\mathrm{p}}$ to be the best among models under consideration.

Table 6
Ten simulated data sets: $N=300, n_{1 .}=150$ and $\boldsymbol{n}_{.1}=120$

| Simulation |  | Estimated population |  |  |  |  | AIC |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Iteration | $n_{11}$ | $\widehat{N}_{\text {o }}$ | $\widehat{N}_{\text {s }}$ | $\widehat{N}_{\text {b }}$ | $\widehat{N}_{\text {a }}$ | $\widehat{N}_{\text {p }}$ | $M_{o}$ | $M_{s}$ | $M_{b}$ | $M_{a}$ | $M_{p}$ |
| 1 | 76 | 1,385,100 | 237 | 212 | 1,415,272 | 243 | 19,453,915 | 59 | 65 | 19,924,124 | 56 |
| 2 | 82 | 1,494,450 | 220 | 201 | 1,554,556 | 235 | 22,833,390 | 69 | 70 | 23,852,432 | 64 |
| 3 | 88 | 1,603,800 | 205 | 191 | 1,694,704 | 228 | 26,496,764 | 75 | 72 | 28,163,305 | 71 |
| 4 | 85 | 1,549,125 | 212 | 196 | 1,624,563 | 231 | 24,629,471 | 72 | 71 | 25,960,373 | 68 |
| 5 | 81 | 1,476,225 | 222 | 203 | 1,531,265 | 236 | 22,250,481 | 68 | 69 | 23,171,024 | 62 |
| 6 | 79 | 1,439,775 | 228 | 206 | 1,484,766 | 239 | 21,108,286 | 64 | 68 | 21,840,191 | 60 |
| 7 | 70 | 1,275,750 | 257 | 225 | 1,277,500 | 250 | 16,356,341 | 43 | 58 | 16,381,234 | 48 |
| 8 | 74 | 1,348,650 | 243 | 216 | 1,369,148 | 245 | 18,390,171 | 54 | 63 | 18,700,303 | 53 |
| 9 | 91 | 1,658,475 | 198 | 186 | 1,764,900 | 224 | 28,435,498 | 76 | 72 | 30,460,281 | 75 |
| 10 | 87 | 1,585,575 | 207 | 192 | 1,671,314 | 229 | 25,866,406 | 74 | 71 | 27,418,493 | 70 |
| MAD |  | 1,481,393 | 77 | 97 | 1,538,499 | 64 |  |  |  |  |  |

$M_{\mathrm{p}}$ shows a much better estimate than any other model in Table 6.

Table 7
Ten simulated data sets: $\boldsymbol{N}=\mathbf{5 0 0}, \boldsymbol{n}_{\mathbf{1} .}=\mathbf{1 5 0}$ and $\boldsymbol{n}_{.1}=\mathbf{5 0}$

| Simulation |  | Estimated population |  |  |  |  | AIC |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Iteration | $n_{11}$ | $\widehat{N}_{o}$ | $\widehat{N}_{s}$ | $\widehat{N}_{b}$ | $\widehat{N}_{a}$ | $\widehat{N}_{p}$ | $M_{o}$ | $M_{s}$ | $M_{b}$ | $M_{a}$ | $M_{p}$ |
| 1 | 40 | 400,000 | 188 | 161 | 578,000 | 480 | 2,696,754 | 197 | 171 | 4,068,376 | 31 |
| 2 | 35 | 350,000 | 214 | 167 | 494,813 | 495 | 2,031,665 | 185 | 156 | 2,993,276 | 10 |
| 3 | 43 | 430,000 | 174 | 157 | 628,897 | 471 | 3,143,421 | 199 | 179 | 4,804,559 | 46 |
| 4 | 37 | 370,000 | 203 | 164 | 527,824 | 489 | 2,285,859 | 191 | 162 | 3,400,839 | 18 |
| 5 | 37 | 370,000 | 203 | 164 | 527,824 | 489 | 2,285,859 | 191 | 162 | 3,400,839 | 18 |
| 6 | 41 | 410,000 | 183 | 160 | 594,890 | 477 | 2,841,655 | 198 | 174 | 4,306,081 | 36 |
| 7 | 35 | 350,000 | 214 | 167 | 494,813 | 495 | 2,031,665 | 185 | 156 | 2,993,276 | 10 |
| 8 | 35 | 350,000 | 214 | 167 | 494,813 | 495 | 2,031,665 | 185 | 156 | 2,993,276 | 10 |
| 9 | 38 | 380,000 | 197 | 163 | 544,464 | 486 | 2,418,866 | 193 | 165 | 3,615,805 | 22 |
| 10 | 43 | 430,000 | 174 | 157 | 628,897 | 471 | 3,143,421 | 199 | 179 | 4,804,559 | 46 |
| MAD |  | 383,500 | 304 | 337 | 551,023 | 15 |  |  |  |  |  |

In Table 7, $M_{\mathrm{p}}$ has the smallest MAD and AIC values as well as most reasonable estimate of the population size.

Table 8
Ten simulated data sets: $N=500, n_{1 .}=150$ and $\boldsymbol{n}_{.1}=100$

| Simulation |  | Estimated population |  |  |  |  | AIC |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Iteration | $n_{11}$ | $\widehat{N}_{o}$ | $\widehat{N}_{s}$ | $\widehat{N}_{b}$ | $\widehat{N}_{a}$ | $\widehat{N}_{p}$ | $M_{o}$ | $M_{s}$ | $M_{b}$ | $M_{a}$ | $M_{p}$ |
| 1 | 77 | 1,203,125 | 195 | 177 | 1,379,109 | 260 | 17,024,961 | 222 | 187 | 19,806,099 | 282 |
| 2 | 79 | 1,234,375 | 190 | 174 | 1,422,356 | 257 | 17,971,039 | 218 | 185 | 21,027,366 | 288 |

| MAD |  | 3,111,000 | 614 | 676 | 4,475,902 | 33 |  |  |  |  |  |

Table 10 shows the efficacy of $M_{\mathrm{p}}$, both in AIC and MAD values as well as the estimates of the population size.

### 4.1. Discussion of the simulation study

$M_{\mathrm{p}}$ model performed better than any other model under consideration in terms of AIC and MAD values as well as closely approximating the corresponding hypothetical population sizes in Tables 1-10. The consistency of the MAD values and the closeness of estimates to the hypothetical population sizes show $M_{\mathrm{p}}$ to be more reliable in estimating disproportionate two-sample capture-recapture population size. This reveals that the proposed model is more efficient than any of the other four models as the AIC values appear to be much smaller when the ratio of the first sample and second sample is directly proportional to the ratio of the hypothesized population to the first sample.

## 5. Conclusion

Heterogeneity of clusters within a lot and relatively small sample sizes are the albatross associated with LQAS and making it susceptible to Type I or/and Type II errors given the large size of the population targeted for vaccination, hence the need to come up with a complementary tool which would not incur additional cost but to address the pitfalls in LQAS. CRC techniques addresses the issues of heterogeneity and takes into account the relatively small sample size by incorporating the SIAs coverage side by side with the LQAS coverage thereby mitigating the error accruable from heterogeneity and small sample size associated with LQAS.

There are number of CRC techniques used for estimating population size of a close population. Some of these techniques include: Petersen model, No Effect model, Behavioral mode, Efficient model for high recapture to mention but a few. The application of any of the mentioned models is encumber on satisfying the assumptions associated with each of them. SIAs immunization records and LQAS are a typology of C-R method with peculiarity to the disproportionality between the first sample (SIAs house-to-house) and the second sample (LQAS). Consequently, the need to develop a model that addresses this disproportionality.

A disproportionate C-R model was proposed and was compared against some existing C-R models using simulated data, AIC and MAD. The results showed that the AIC and MAD of the proposed model were the smallest compared to No factor, Petersen, Behavioral and Effective model for high recaptures when the ratio of the estimated population size to the first sample size is approximately equal to the ratio of the first sample to the second sample sizes in forestalling the disparity between first sample and second sample sizes in two-sample C-R associated to SIAs data.

## Conflicts of Interest

The authors declare that they have no conflicts of interest to this work.
